

Project – Rent Calculator

```
rent = int(input(" Enter your flat rent :- "))

electricity_current_unit_reading = int(input(" Enter the current meter reading :- "))

electricity_previous_unit_reading = int(input(" Enter the previous meter reading :- "))

charge_per_unit = int(input(" Enter charge per unit :- "))

water_charge = int(input(" Enter the charges of water :- "))

calculated_electricity_unit = (electricity_current_unit_reading -
electricity_previous_unit_reading)

print("Electricity unit spend :",calculated_electricity_unit)

total_electricity_bill = (calculated_electricity_unit * charge_per_unit)

print("Electricity bill :",total_electricity_bill)

water_charge_bill = water_charge

print("Water charges :",water_charge_bill)

total_rent = (rent + total_electricity_bill + water_charge_bill)

print("The renter want to pay the rent :",total_rent)

print("Thank you ...")
```

Steps of Rent Calculator Project –

a) Input Collection

- The program first asks the user to enter:
 - Flat rent (`rent`)
 - Current electricity meter reading (`electricity_current_unit_reading`)
 - Previous electricity meter reading (`electricity_previous_unit_reading`)
 - Charge per electricity unit (`charge_per_unit`)
 - Water charges (`water_charge`)
- (Note – These inputs are taken as integers using `int(input(...)).`)

b) Electricity Units Calculation

- Formula : `calculated_electricity_unit = electricity_current_unit_reading - electricity_previous_unit_reading`
- This gives the number of electricity units consumed during the billing period.
- The program prints : `"Electricity unit spend :"`

c) Electricity Bill Calculation

- Formula : `total_electricity_bill = calculated_electricity_unit * charge_per_unit`
- This gives the total electricity bill.
- The program prints : `"Electricity bill : "`

d) Water Charges

- Water charges are directly taken from user input (`water_charge`).
- Assigned to `water_charge_bill`.
- The program prints : `"Water charges : "`

e) Total Rent Calculation

- Formula : `total_rent = rent + total_electricity_bill + water_charge_bill`
- This gives the **final amount** the renter has to pay.
- The program prints : `"The renter want to pay the rent : "`

f) End Message

- Finally, the program prints : `"Thank you ..."`
